

Player Profiling Asset

TUGraz – T3.4E – Apache 2.0 – Client side C#

About this asset

This Asset will be implemented as a client-side component in C#. It is concerned with evaluating the player in an initial questionnaire. Resulting information is supplied to the game in terms of a set of values. The asset contains three predefined questionnaires and an authoring component that allows the modification of these existing questionnaires, as well as the creation of new questionnaires. The asset translates the answer patterns into a small set of values, which can be used by the game to pre-configure itself. The asset architecture will prevent multiple asset creation; only one client-side component of this asset per game is needed.

Asset mechanics

An XML-file containing all necessary information about the questionnaire and the evaluation of the questionnaire is loaded from a local storage. A supplied authoring tool, accessible via the Integrated Authoring (Tool T3.7), creates this XML. Out of this information a data structure is created by the C# asset, which represent the questionnaire. This questionnaire needs to be presented to the player by the game. After filling out the questionnaire the resulting data is sent back to the Asset, which will evaluate the answers and supply the results to the game.

Asset interfaces

For using this Asset proceed like the following:

- The xml questionnaire can be accessed directly:

```
String getQuestionnaireXML()
```

Using a static method this xml String can be transformed to a data-type object containing the questionnaire:

```
QuestionnaireData QuestionnaireData.getQuestionnaireData(xml)
```

- The answers of the questionnaire can be returned for the score calculation by using the following method:

```
Void setAnswers(Dictionary<String,Integer> answers)
```

The resulting score can be accessed (for both options) by the following code snippet:

- The result of the questionnaire will be available as text-value combinations. The value can be requested from the Asset. If null is returned no questionnaire data is available.

```
Dictionary<String,Double> getResults()
```

Asset dependencies/requirements

- GameStorage Asset – used to store questionnaire results

Milestones

Milestone 1

- t1.1: Creating the first version of the design document, defining the API and creating a dummy asset with the API implemented

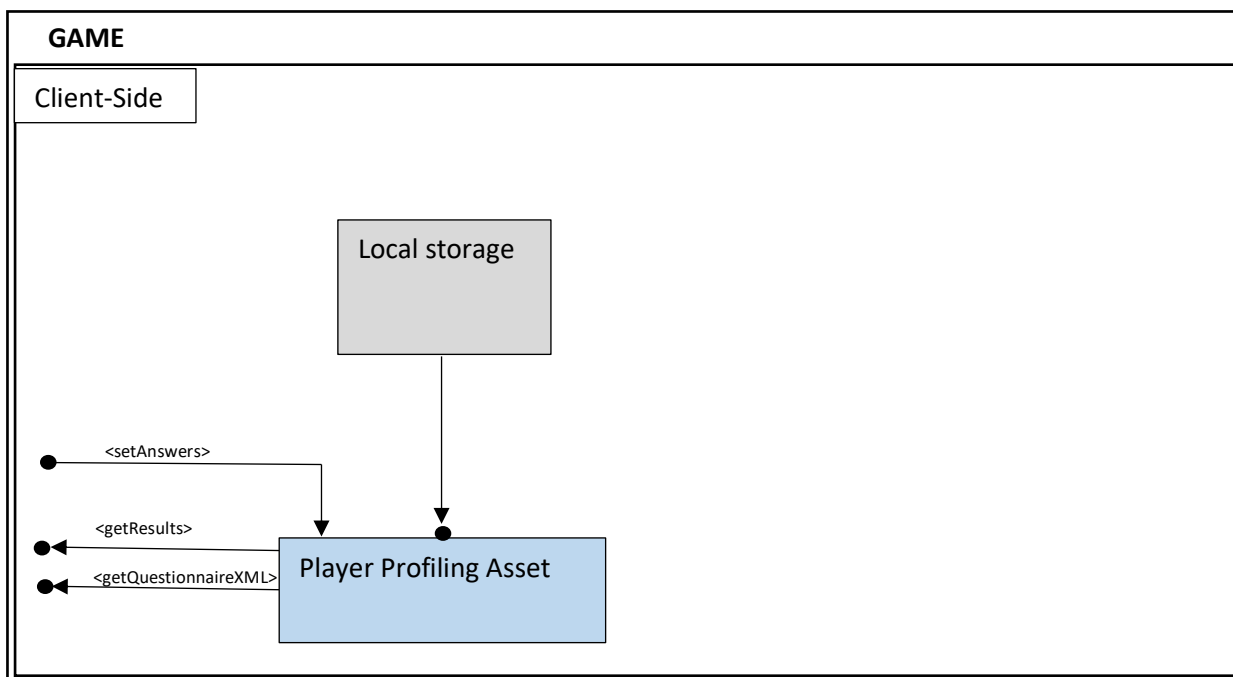

Milestone 2

- t2.1: Elaborate XML-Structure containing questionnaire-data.
- t2.2: Create Software Asset in line with Asset-Manager infrastructure.
- t2.3: Elaborate Settings-structure within the Asset-Manager infrastructure.
- t2.4: Integrate Game Storage functionality into the asset-functionality.
- T2.5: Create Authoring tool for XML-Structure generation

Milestone 3

- t3.1: testing the asset with a game
- t3.2: instructions and scripts for building and deploying

Graphical representation

Set up the Asset

For setting up this Asset there is mainly one things to do (additionally to create the Asset), which is:

- Supply the Questionnaire data via a XML-file to the Asset. Therefore, a JS-HTML tool will be used (more information where to find and how to use this tool will be supplied at a later stage).

The following code can be used to specify the XML file id:

```
PlayerProfilingAsset ppa = PlayerProfilingAsset.Instance;  
PlayerProfilingAssetSettings ppas = new PlayerProfilingAssetSettings ();  
ppas.QuestionnaireDataXMLFileId = "file.xml";  
ppa.Settings = ppas;
```

Use the Asset

The questionnaire data can be requested from the asset using the following code:

```
PlayerProfilingAsset ppa = new PlayerProfilingAsset.Instance;  
String xml = ppa.getQuestionnaireXML();  
QuestionnaireData qd = QuestionnaireData.getQuestionnaireData(xml);
```

Deployment

For the source code the following GitHub-link can be used <https://github.com/RAGE-TUGraz/PlayerProfilingAsset> - it contains the Visual Studio solution of the asset's C# implementation. Furthermore, the broken links to external asset DLLs need to be fixed for each project and the Bridge code need to be adopted to the new environment, e.g. changing the IDataStorage path.

For integration into Unity, the resulting DLLs need to put into a folder in the Unity working-directory.

Unit test

For executing unit tests, the source code need to be open in visual studio and all links need to be fixed. In the test-explorer all tests can be executed.
